Case report 654*

David G. Frankel, M.D., Richard H. Daffner, M.D., and Scott E. Wang, M.D.

1 Department of Diagnostic Radiology and 2 Department of Laboratory Medicine, Allegheny General Hospital and Medical College of Pennsylvania, Allegheny Campus, Pittsburgh, Pennsylvania, USA

Imaging illustrations

Fig. 1. A Frontal and B lateral views show destructive lesions of L5. Note the absent anterior vertebral body line of L4 (arrow) in B. A right psoas mass is present.

Fig. 2. A Chest radiograph shows a right paratracheal mass (open arrow) and a destructive lesion of the right ninth rib (black arrow). B Detailed view of the right ninth rib.

Clinical information

This 28-year-old black man presented with a 1-month history of increasing pain in the lower back and both legs. He denied any paresthesias, subjective weakness or weight loss. Physical examination was unremarkable.

Laboratory examination revealed white blood cell count (WBC) of 19.7, hemoglobin/hematocrit (Hb/hct) of 11.8/36.4, phosphorous of 5.0, albumin of 3.3, and alkaline phosphatase of 144. The serum was human immunodeficiency virus (HIV) negative.

Plain radiographs of the lumbar spine (Fig. 1) showed a destructive lesion of L5 with an associated mass in the right psoas region. The body of L4 was also involved.

Subsequent chest radiographs (Fig. 2) disclosed hilar adenopathy and a lytic lesion of the ninth rib. Computed tomograms (CT) of the lumbar spine revealed multiple bone lesions in the vertebrae and pelvis (Fig. 3). Magnetic resonance imaging (MRI) examination showed a vertebra plana of L5, multiple lesions of low signal intensity, and a paravertebral soft tissue mass at L5 (Fig. 4).

The patient underwent biopsies of the lumbar mass and an enlarged supraclavicular lymph node.
